- 1 Introduction
- 2 Deterministic 3-Way ORWW-Automata
- 3 Deterministic Extended 2-Way ORWW-Automata
- 4 On the Language Class  $\mathcal{L}(\text{det-2D-x2W-ORWW})$
- 5 Concluding Remarks

# 1. Introduction

The **restarting automaton** models the linguistic technique of **analysis by reduction** (Jančar et. al., 1995).

Various classes of formal languages have been characterized by certain types of restarting automata:

- REG : R(1)-automata (Mráz, 2001)
- REG : det-RR(1) (Reimann, 2007)
- DCFL : det-mon-R(R)(W)(W) (Jančar et. al., 1999)
- CFL : mon-R(R)WW-automata (Jančar et. al., 1999)
- CRL : det-R(R)WW-automata (Niemann et. al., 1998)
- GCSL : wmon-R(R)WW-automata (Jurdziński et. al., 2004)

Many studies have extended grammars and automata from word languages to picture languages, e.g.:

- 4-way finite automata (Blum, Hewitt 1967),
- isometric array grammars (Rosenfeld 1971),
- matrix grammars (Siromoney et. al. 1972),
- tiling systems and automata (Giammarresi, Restivo 1992),
- Sudoku-deterministically recognizable languages (Borchert, Reinhardt 2007).

The class REC of recognizable picture languages has been identified as a central class:

- various nice characterizations and
- good closure properties,
- but it contains NP-complete languages, that is, NP-complete membership problems (Lindgren et. al. 1998).

Many studies have extended grammars and automata from word languages to picture languages, e.g.:

- 4-way finite automata (Blum, Hewitt 1967),
- isometric array grammars (Rosenfeld 1971),
- matrix grammars (Siromoney et. al. 1972),
- tiling systems and automata (Giammarresi, Restivo 1992),
- Sudoku-deterministically recognizable languages (Borchert, Reinhardt 2007).

The class REC of recognizable picture languages has been identified as a central class:

- various nice characterizations and
- good closure properties,
- but it contains NP-complete languages, that is, NP-complete membership problems (Lindgren et. al. 1998).

Quest for two-dimensional automata with the following properties:

- **intuitive model**, that is, easy way of designing algorithms (automata) for interesting languages,
- **membership problems** decidable in **polynomial time**,
- restricted to word languages, only the **regular languages** should be accepted,
- nice **closure properties**.

Several models have been proposed recently:

- the **restarting tiling automaton** (Průša, Mráz, CIAA 2012)
- the **Sgraffito automaton** (Průša, Mráz, DLT 2012)
- the **deterministic 2-dimensional 3-way ordered restarting automaton** (Mráz, Otto, SOFSEM 2014)

Here: the **determ. 2-dim. extended 2-way ordered restarting automaton** (**det-2D-x2W-ORWW-automaton**).

## 2. Deterministic 3-Way ORWW-Automata

A **picture**  $P$  over  $\Sigma$  is a finite two-dimensional array of symbols from  $\Sigma$ .  $\text{row}(P)$  ( $\text{col}(P)$ ) denotes the number of **rows** (**columns**) of  $P$ ,  $P(i, j)$  is the symbol at position  $(i, j)$ ,  $1 \leq i \leq \text{row}(P)$ ,  $1 \leq j \leq \text{col}(P)$ . By  $\Sigma^{m,n}$  we denote the set of all pictures of size  $m \times n$  over  $\Sigma$ , and  $\Sigma^{*,*}$  is the set of all pictures over  $\Sigma$ .

Let  $\mathcal{S} = \{\vdash, \dashv, \top, \perp, \#\}$  be a set of five special markers (**sentinels**).

In order to enable an automaton to detect the border of  $P$  easily, we define the **boundary picture**  $\hat{P}$  over  $\Sigma \cup \mathcal{S}$  of size  $(m+2) \times (n+2)$ :

#	$\top$	$\top$	$\dots$	$\top$	$\top$	#
$\vdash$	$P$					$\dashv$
$\vdots$						$\dashv$
$\vdash$						$\dashv$
#	$\perp$	$\perp$	$\dots$	$\perp$	$\perp$	#

#	$\perp$	$\perp$	$\dots$	$\perp$	$\perp$	#

## Definition 1

*Deterministic two-dimensional three-way ordered RWW-automaton*

$M = (Q, \Sigma, \Gamma, \mathcal{S}, q_0, \delta, >)$ :

- $Q$  is a finite set of states containing the initial state  $q_0$ ,
- $\Sigma$  is a finite input alphabet,  $\Gamma$  is a finite tape alphabet containing  $\Sigma$  such that  $\Gamma \cap \mathcal{S} = \emptyset$
- $>$  is a partial ordering on  $\Gamma$
- $\delta$  is the transition function,  
for each  $C = \begin{array}{|c|c|c|} \hline & & \\ \hline & a & \\ \hline & & \\ \hline \end{array}$

it holds at most one of the following:

- $\delta(q, C) = (q', R)$  – move right step
- $\delta(q, C) = (q', D)$  – move down step
- $\delta(q, C) = (q', U)$  – move up step
- $\delta(q, C) = b$  and  $a > b$  – rewrite and restart

## Theorem 2

$\mathcal{L}(\text{det-2D-3W-ORWW}) \subseteq \text{DTIME}((\text{size}(P))^2)$ .

## Theorem 3 (M., O., SOFSEM 2014)

$\mathcal{L}(\text{det-2D-3W-ORWW}) \cap \Sigma^{1,*} = \text{REG}(\Sigma)$ , that is, the det-2D-3W-ORWW-automaton only accepts regular word languages.

## Theorem 4 (M., O., SOFSEM 2014)

The det-2D-3W-ORWW-automaton can simulate the *deterministic Sgraffito automaton*, which in turn is known to be able to simulate

- (alternating) four-way finite automata,
- deterministic four-way one-marker automata,
- and to accept all sudoku-deterministically recognizable languages.

## Theorem 2

$$\mathcal{L}(\text{det-2D-3W-ORWW}) \subseteq \text{DTIME}((\text{size}(P))^2).$$

## Theorem 3 (M., O., SOFSEM 2014)

$\mathcal{L}(\text{det-2D-3W-ORWW}) \cap \Sigma^{1,*} = \text{REG}(\Sigma)$ , that is, the *det-2D-3W-ORWW-automaton* only accepts regular word languages.

## Theorem 4 (M., O., SOFSEM 2014)

The *det-2D-3W-ORWW-automaton* can simulate the *deterministic Sgraffito automaton*, which in turn is known to be able to simulate

- (alternating) four-way finite automata,
- deterministic four-way one-marker automata,
- and to accept all sudoku-deterministically recognizable languages.

## Theorem 2

$$\mathcal{L}(\text{det-2D-3W-ORWW}) \subseteq \text{DTIME}((\text{size}(P))^2).$$

## Theorem 3 (M., O., SOFSEM 2014)

$\mathcal{L}(\text{det-2D-3W-ORWW}) \cap \Sigma^{1,*} = \text{REG}(\Sigma)$ , that is, the *det-2D-3W-ORWW-automaton* only accepts regular word languages.

## Theorem 4 (M., O., SOFSEM 2014)

The *det-2D-3W-ORWW-automaton* can simulate the *deterministic Sgraffito automaton*, which in turn is known to be able to simulate

- (alternating) four-way finite automata,
- deterministic four-way one-marker automata,
- and to accept all sudoku-deterministically recognizable languages.

## Remarks

- The det-2D-3W-ORWW-automata clearly favour vertical over horizontal movements. Accordingly,  $\mathcal{L}(\text{det-2D-3W-ORWW})$  is **not closed** under transposition.

- It could happen that a det-2D-3W-ORWW-automaton  $M$  **does not terminate** on some input picture, as it may get stuck on a column, just moving up and down.

To avoid this, it is **required explicitly** that  $M$  halts on all input pictures!

This can be realized by providing a **simple pattern**, e.g.,  $\text{up}^* - \text{down}^* - \text{up}^* - \text{down}^*$ , such that on each column, the sequence of up and down movements must fit this pattern, or one could use an **external counter** that counts the number of uninterrupted up and down movements on a column.

## Remarks

- The det-2D-3W-ORWW-automata clearly favour vertical over horizontal movements. Accordingly,  $\mathcal{L}(\text{det-2D-3W-ORWW})$  is **not closed** under transposition.

### 3. Deterministic Extended 2-Way ORWW-Automata

#### Definition 5

A *deterministic two-dimensional extended two-way ordered RWW-automaton* (*det-2D-x2W-ORWW-automaton*) is given through a 7-tuple

$$M = (Q, \Sigma, \Gamma, \mathcal{S}, q_0, \delta, >),$$

where all components are defined as for *det-2D-3W-ORWW-automata*. However, the set of possible head movements is restricted to

$$\mathcal{H} = \{\mathbf{R}, \mathbf{D}\},$$

where the *move-right* and *move-down* steps are extended as follows:

## Definition 5 (cont.)

## Extended Move-Right Step:

picture

#	⊥	⊥	⊥	⊥	#
⊢	0	0	0	1	⊣
⊢	1	0	0	0	⊣
⊢	0	1	0	0	⊣
⊢	0	0	1	0	⊣
#	⊥	⊥	⊥	⊥	#

$q_1$

finite control

## Definition 5 (cont.)

## Extended Move-Right Step:

┌	0	1	0	0	┐
┌	0	0	1	0	┐
#	⊥	⊥	⊥	⊥	#

$q_4$

finite control

## Definition 5 (cont.)

In any cycle,  $M$  can only use extended move-right or extended move-down steps, **but not both!**

$M$  is a **stateless** det-2D-x2W-ORWW-automaton (**stl-det-2D-x2W-ORWW-automaton**) if it has just a single state. For such an automaton, the components  $Q$  and  $q_0$  are suppressed.

## Corollary 6

*When restricted to one-dimensional input, then the det-2D-x2W-ORWW-automaton just accepts the regular word languages. This also holds for the stateless variant.*

## Theorem 7

$\mathcal{L}(\text{det-2D-x2W-ORWW}) \subseteq \text{DTIME}((\text{size}(P))^3)$ .

## Definition 5 (cont.)

## Theorem 7

$$\mathcal{L}(\text{det-2D-x2W-ORWW}) \subseteq \text{DTIME}((\text{size}(P))^3).$$

## Example 1

Let  $\Sigma = \{0, 1\}$ , and let

$$L_{\text{perm}} = \{ P \in \Sigma^{*,*} \mid \text{row}(P) = \text{col}(P) \geq 1, \text{ each row and each column contains exactly one symbol } 1 \}.$$

We describe a stl-det-2D-x2W-ORWW-automaton  $M_{\text{perm}}$  for  $L_{\text{perm}}$ .

Let

$$\Gamma = \Sigma \cup \{0', 1', 0'_1, 0'', 1'', 0''_1\},$$

and let

$$1 > 0 > 1' > 0' > 0'_1 > 1'' > 0'' > 0''_1.$$

The automaton  $M_{\text{perm}}$  proceeds as follows:

## Example 1

Let  $\Sigma = \{0, 1\}$ , and let

$$L_{\text{perm}} = \{ P \in \Sigma^{*,*} \mid \text{row}(P) = \text{col}(P) \geq 1, \text{ each row and each column contains exactly one symbol } 1 \}.$$

We describe a stl-det-2D-x2W-ORWW-automaton  $M_{\text{perm}}$  for  $L_{\text{perm}}$ .

Let

## 4. On the Language Class $\mathcal{L}(\text{det-2D-x2W-ORWW})$

### Theorem 8

*The stateless det-2D-x2W-ORWW-automaton can simulate the deterministic Sgraffito automaton.*

### Theorem 9

*The classes of picture languages  $\mathcal{L}(\text{det-2D-x2W-ORWW})$  and  $\mathcal{L}(\text{stl-det-2D-x2W-ORWW})$  are closed under transposition, union, intersection, and complementation.*

## 4. On the Language Class $\mathcal{L}(\text{det-2D-x2W-ORWW})$

### Theorem 8

*The stateless det-2D-x2W-ORWW-automaton can simulate the deterministic Sgraffito automaton.*

### Theorem 9

*The classes of picture languages  $\mathcal{L}(\text{det-2D-x2W-ORWW})$  and  $\mathcal{L}(\text{stl-det-2D-x2W-ORWW})$  are closed under transposition, union, intersection, and complementation.*

In (M., O., SOFSEM 2014) it is shown that the language

$$L_{1\text{col}} = \{ P \in \Sigma^{2n,1} \mid P(1,1) \dots P(n,1) = (P(n+1,1) \dots P(2n,1))^R \},$$

is accepted by a det-2D-3W-ORWW-automaton.

The transpose  $L_{1\text{col}}^t$  of this language is essentially the word language

$$L_{\text{pal}} = \{ w \in \{a, b\}^* \mid |w| \equiv 0 \pmod{2} \text{ and } w = w^R \} \notin \text{REG}.$$

Hence,  $L_{1\text{col}}$  is not accepted by any det-2D-x2W-ORWW-automaton, i.e., there are det-2D-3W-ORWW-automata which cannot be simulated by det-2D-x2W-ORWW-automata.

However, also the converse holds.

## Example 2

Let  $L_{\text{pal},2}$  be the following picture language over  $\Sigma = \{a, b, \square\}$ :

$$L_{\text{pal},2} = \{ P \in \Sigma^{2,2n} \mid P(1,1) \dots P(1,n) = (P(1,n+1) \dots P(1,2n))^R, \\ P(1,i) \in \{a,b\} \text{ and } P(2,i) = \square, 1 \leq i \leq 2n \},$$

that is,  $L_{\text{pal},2}$  consists of all two-row pictures such that the first row contains a palindrome of even length over  $\{a, b\}$ , and the second row just contains  $\square$ -symbols.

We describe a det-2D-x2W-ORWW-automaton  $M_{\text{pal},2}$  for  $L_{\text{pal},2}$ .

Let

$$\Gamma = \Sigma \cup \{a_1, a_2, b_1, b_2, \uparrow_1, \uparrow_2\},$$

and let

$$a > b > a_1 > b_1 > a_2 > b_2 > \square > \uparrow_1 > \uparrow_2.$$

The automaton  $M_{\text{pal},2}$  proceeds as follows:

## Example 2

Let  $L_{\text{pal},2}$  be the following picture language over  $\Sigma = \{a, b, \square\}$ :

$$L_{\text{pal},2} = \{ P \in \Sigma^{2,2n} \mid P(1,1) \dots P(1,n) = (P(1,n+1) \dots P(1,2n))^R, \\ P(1,i) \in \{a,b\} \text{ and } P(2,i) = \square, 1 \leq i \leq 2n \},$$

that is,  $L_{\text{pal},2}$  consists of all two-row pictures such that the first row contains a palindrome of even length over  $\{a, b\}$ , and the second row just contains  $\square$ -symbols.

We describe a det-2D-x2W-ORWW-automaton  $M_{\text{pal},2}$  for  $L_{\text{pal},2}$ .

Let

$$\Gamma = \Sigma \cup \{a_1, a_2, b_1, b_2, \uparrow_1, \uparrow_2\},$$

and let

$$a > b > a_1 > b_1 > a_2 > b_2 > \square > \uparrow_1 > \uparrow_2.$$

The automaton  $M_{\text{pal},2}$  proceeds as follows:

## Proposition 10

$L_{\text{pal},2} \notin \mathcal{L}(\text{det-2D-3W-ORWW})$ .

## Corollary 11

*The class of picture languages  $\mathcal{L}(\text{det-2D-x2W-ORWW})$  is incomparable under inclusion to the class of picture languages  $\mathcal{L}(\text{det-2D-3W-ORWW})$ .*

## Proposition 12

$L_{\text{pal},2} \notin \mathcal{L}(\text{stl-det-2D-x2W-ORWW})$ .

## Theorem 13

$\mathcal{L}(\text{stl-det-2D-x2W-ORWW}) \subsetneq \mathcal{L}(\text{det-2D-x2W-ORWW})$ .

## Proposition 12

$L_{\text{pal},2} \notin \mathcal{L}(\text{stl-det-2D-x2W-ORWW})$ .

## Theorem 13

$\mathcal{L}(\text{stl-det-2D-x2W-ORWW}) \subsetneq \mathcal{L}(\text{det-2D-x2W-ORWW})$ .

## Proof outline of Prop. 12.

Assume that  $M = (\Sigma, \Gamma, \mathcal{S}, \delta, \triangleright)$  is a stl-det-2D-x2W-ORWW-automaton over  $\Sigma = \{a, b, \square\}$  such that  $L(M) = L_{\text{pal},2}$ .

For  $w = a_1 \dots a_n$ , where  $n \geq 1$  and  $a_1, \dots, a_n \in \{a, b\}$ , let

$$P_w = \begin{bmatrix} a_1 & \dots & a_n & a & a & a_n & \dots & a_1 \\ \square & \dots & \square & \square & \square & \square & \dots & \square \end{bmatrix} \in L_{\text{pal},2}.$$

Given  $P_w$  as input,  $M$  will perform an accepting computation, which can be split into a finite number of **phases**, where we distinguish between four types of phases:

- A **left-only phase** consists of a sequence of cycles in which the window of  $M$  stays on the left half of the picture.
- An **upper-right phase** consists of a sequence of cycles in which all rewrite steps are performed on the right half of the picture, and in addition, in the first of these cycles,  $M$  enters the right half of the picture through a move-right step in row 1.

## Proof outline of Prop. 12.

Assume that  $M = (\Sigma, \Gamma, \mathcal{S}, \delta, \triangleright)$  is a stl-det-2D-x2W-ORWW-automaton over  $\Sigma = \{a, b, \square\}$  such that  $L(M) = L_{\text{pal},2}$ .

For  $w = a_1 \dots a_n$ , where  $n \geq 1$  and  $a_1, \dots, a_n \in \{a, b\}$ , let

$$P_w = \begin{bmatrix} a_1 & \dots & a_n & a & a & a_n & \dots & a_1 \\ \square & \dots & \square & \square & \square & \square & \dots & \square \end{bmatrix} \in L_{\text{pal},2}.$$

Given  $P_w$  as input,  $M$  will perform an accepting computation, which can be split into a finite number of **phases**, where we distinguish between four types of phases:

- A **left-only phase** consists of a sequence of cycles in which the window of  $M$  stays on the left half of the picture.
- An **upper-right phase** consists of a sequence of cycles in which all rewrite steps are performed on the right half of the picture, and in addition, in the first of these cycles,  $M$  enters the right half of the picture through a move-right step in row 1.

## Proof outline of Prop. 12.

Assume that  $M = (\Sigma, \Gamma, \mathcal{S}, \delta, \triangleright)$  is a stl-det-2D-x2W-ORWW-automaton over  $\Sigma = \{a, b, \square\}$  such that  $L(M) = L_{\text{pal},2}$ .

For  $w = a_1 \dots a_n$ , where  $n \geq 1$  and  $a_1, \dots, a_n \in \{a, b\}$ , let

$$P_w = \begin{bmatrix} a_1 & \dots & a_n & a & a & a_n & \dots & a_1 \\ \square & \dots & \square & \square & \square & \square & \dots & \square \end{bmatrix} \in L_{\text{pal},2}.$$

Given  $P_w$  as input,  $M$  will perform an accepting computation, which can be split into a finite number of **phases**, where we distinguish between four types of phases:

- A **left-only phase** consists of a sequence of cycles in which the window of  $M$  stays on the left half of the picture.
- An **upper-right phase** consists of a sequence of cycles in which all rewrite steps are performed on the right half of the picture, and in addition, in the first of these cycles,  $M$  enters the right half of the picture through a move-right step in row 1.

## Proof outline of Prop. 12.

Assume that  $M = (\Sigma, \Gamma, \mathcal{S}, \delta, \triangleright)$  is a stl-det-2D-x2W-ORWW-automaton over  $\Sigma = \{a, b, \square\}$  such that  $L(M) = L_{\text{pal},2}$ .

For  $w = a_1 \dots a_n$ , where  $n \geq 1$  and  $a_1, \dots, a_n \in \{a, b\}$ , let

$$P_w = \begin{bmatrix} a_1 & \dots & a_n & a & a & a_n & \dots & a_1 \\ \square & \dots & \square & \square & \square & \square & \dots & \square \end{bmatrix} \in L_{\text{pal},2}.$$

Given  $P_w$  as input,  $M$  will perform an accepting computation, which can be split into a finite number of **phases**, where we distinguish between four types of phases:

- A **left-only phase** consists of a sequence of cycles in which the window of  $M$  stays on the left half of the picture.
- An **upper-right phase** consists of a sequence of cycles in which all rewrite steps are performed on the right half of the picture, and in addition, in the first of these cycles,  $M$  enters the right half of the picture through a move-right step in row 1.

## Proof outline (cont.)

- A **lower-left phase** is a sequence of cycles in which all rewrite steps are performed in the left half of the picture, and in addition, the first of these cycles contains an extended move-right step.
- A **lower-right phase** is a sequence of cycles in which all rewrite steps are performed in the right half of the picture, and in addition, in the first of these cycles,  $M$  enters the right half of the picture through a move-right step in row 2 or through an extended move-down step.

The sequence of cycles of the computation of  $M$  on input  $P_w$  can uniquely be split into a sequence of phases of maximum length.

Thus, this computation can be described in a unique way by a string  $\alpha$  over the alphabet  $\Omega = \{O, U, L, R\}$ , where  $O$  denotes a left-Only phase,  $U$  stands for an Upper-right phase,  $L$  denotes a lower-Left phase, and  $R$  stands for a lower-Right phase.

## Proof outline (cont.)

- A **lower-left phase** is a sequence of cycles in which all rewrite steps are performed in the left half of the picture, and in addition, the first of these cycles contains an extended move-right step.
- A **lower-right phase** is a sequence of cycles in which all rewrite steps are performed in the right half of the picture, and in addition, in the first of these cycles,  $M$  enters the right half of the picture through a move-right step in row 2 or through an extended move-down step.

The sequence of cycles of the computation of  $M$  on input  $P_w$  can uniquely be split into a sequence of phases of maximum length.

Thus, this computation can be described in a unique way by a string  $\alpha$  over the alphabet  $\Omega = \{O, U, L, R\}$ , where  $O$  denotes a left-Only phase,  $U$  stands for an Upper-right phase,  $L$  denotes a lower-Left phase, and  $R$  stands for a lower-Right phase.

## Proof outline (cont.)

- A **lower-left phase** is a sequence of cycles in which all rewrite steps are performed in the left half of the picture, and in addition, the first of these cycles contains an extended move-right step.
- A **lower-right phase** is a sequence of cycles in which all rewrite steps are performed in the right half of the picture, and in addition, in the first of these cycles,  $M$  enters the right half of the picture through a move-right step in row 2 or through an extended move-down step.

The sequence of cycles of the computation of  $M$  on input  $P_w$  can uniquely be split into a sequence of phases of maximum length.

Thus, this computation can be described in a unique way by a string  $\alpha$  over the alphabet  $\Omega = \{O, U, L, R\}$ , where  $O$  denotes a left-Only phase,  $U$  stands for an Upper-right phase,  $L$  denotes a lower-Left phase, and  $R$  stands for a lower-Right phase.

## Proof outline (cont.)

Concerning the possible changes from one phase to the next there are some restrictions based on the fact that  $M$  is stateless, e.g.,

- while  $M$  is in a lower-right phase ( $R$ ), it just moves through the left half of the current picture after each rewrite/restart step. Thus,  $M$  cannot get into another phase until it performs a rewrite step that replaces a symbol in the first column of the right half of the picture. However, in a fixed column, less than  $2 \cdot |\Gamma|$  many rewrite steps can be performed, and so  $|\alpha|_R \leq 1 + 2 \cdot |\Gamma|$ .

It can be shown that

$$|\alpha| \leq |\alpha|_O + |\alpha|_R + |\alpha|_L + |\alpha|_U \leq 15 + 28 \cdot |\Gamma|,$$

i.e., each computation of  $M$  consists of  $\leq 15 + 28 \cdot |\Gamma|$  many phases.

Using a notion of **generalized crossing sequence** and counting arguments it can now be shown that  $M$  will also accept some pictures that do not belong to the language  $L_{\text{pal},2}$ , a **contradiction!** □

## 5. Concluding Remarks

The det-2D-x2W-ORWW-automaton has the following nice properties:

- The membership problem for the picture languages accepted is decidable in polynomial time.
- It is even more expressive than the deterministic Sgraffito automaton.
- It only accepts regular word languages.
- It avoids the artificial termination condition of the det-2D-3W-ORWW-automaton.

## 5. Concluding Remarks
